With the electrolyte and electro-active materials stored externally, true flow batteries have many advantages, one of which is the separation of the power and energy requirements.

In this paper, a new approach is proposed to surpass the solubility limit by manipulating the solvation structure with polycomplex ion additives (PIA).

The gel polymer electrolyte, specifically developed to overcome these limitations, improves Li+ diffusion, mass transport, and energy density.

Here, the transport properties of various types of electrolytes in redox flow batteries are reviewed, including viscosity, diffusion coefficient, and conductivity.
